

APPENDIX 1

Results of pollen and plant macro-remain analyses, radiocarbon dating and description of sediment lithology

Biostratigraphy (Mangerud et al., 1974; age cal BP – ¹ Litt et al., 2001; ² Starkel et al., 2013)	Depth [cm]	Sediment	Results of analyses (pollen spectra*, other analyses**)
End of the Plenivistulian before 14450 ¹ cal BP	PI: 1430–900.	PI: grey organic silt, laminated in part (1205– 1198cm).	<p style="text-align: center;"><u>L PAZ: PI: NAP–Pinus–Betula</u> <u>Pollen spectra:</u></p> <p>P: dominance of <i>Pinus sylvestris</i> (mean: 43.13%) and NAP (mean: over 20.0%). The highest content of <i>Juniperus communis</i> (maximum: 4.5%) and <i>Betula nana</i> (maximum: 9.0%). Pollen grains of <i>Ephedra</i>, <i>Populus</i> and <i>Hippophæ rhamonides</i> appear. Among herbaceous plants, an absolute maximum is attained by Apiaceae (20.0%) and <i>Artemisia</i> (5.0%), accompanied by high amounts of Poaceae (mean: 5.74%) and Cyperaceae (mean: 3.53%). Taxa such as Chenopodiaceae, <i>Dryas octopetala</i>, <i>Helianthemum</i>, <i>Saxifraga</i>, and <i>Selaginella selaginoides</i> are recorded as well. Numerous broken and redeposited pollen grains of <i>Corylus avellana</i>, <i>Ulmus</i>, <i>Tilia</i>, <i>Alnus</i>, <i>Quercus</i>, <i>Fraxinus</i>, <i>Carpinus betulus</i>, <i>Fagus sylvatica</i>, and <i>Picea abies</i>, as well as Neogene grains, are observed (Fig. 7).</p> <p style="text-align: center;"><u>Concentration of pollen grains:</u> PI: below $25 \times 10^5/\text{cm}^3$.</p> <p style="text-align: center;"><u>Radiocarbon dating:</u></p> <p>PI: depth of 1200 cm, 19368–18901 cal BP (95.4%) (15850 ± 80 BP conv., Poz–46881) – organic sediment was dated; depth of 940 cm, 38081–35540 cal BC (95.4%) (32530 ± 460 BP conv., Poz–46880) – organic sediment was dated.</p>
pre–Allerød before 13350 ¹ cal BP	GI: 875–873; GII: 1515–1501.	GI: grey organic silt; GII: grey organic silt (1520– 1505 cm), detritus (1505– 1502 cm) and mineral (1502–1501 cm) gyttja.	<p style="text-align: center;"><u>L PAZ: GI: Pinus–NAP, GII: Pinus–NAP</u> <u>Pollen spectra:</u></p> <p>dominance of <i>Pinus sylvestris</i> (mean: 45.5% – GI, 80.0% – GII) and low content of <i>Betula</i> (mean: 37.4% – GI, 9.5% – GII). NAP content up to several percent, dominated by Poaceae, Cyperaceae and <i>Cichorioideae</i> (Figs. 4 and 5).</p> <p style="text-align: center;"><u>Concentration of pollen grains:</u> GI: below $50 \times 10^5/\text{cm}^3$, GII: below $40 \times 10^5/\text{cm}^3$.</p> <p style="text-align: center;"><u>Macro–remain analysis:</u></p> <p>GII: low content of plant remains; oospores of Characeae, ephiphidia of <i>Daphnia</i>, statoblasts of <i>Cristatella mucedo</i>, and small pieces of charcoal are present.</p> <p style="text-align: center;"><u>Radiocarbon dating:</u></p> <p>GII: depth of 1508 cm, 13580–12740 cal BC (95.4%) (11340 ± 220 BP conv., Gd–19149) – organic sediment was dated.</p>
Allerød 12680–13350 ¹ cal BP	GI: 873–860; GII: 1501–1475; GV: 482–476.	GI: peat (to 865 cm), carbonate gyttja; GII: mineral (to 1490 cm) and detritus gyttja; GV: peat.	<p style="text-align: center;"><u>L PAZ: GI: Pinus–Betula, GII: Pinus–Betula, GV: Pinus–NAP.</u> <u>Pollen spectra:</u></p> <p>G: dominance of <i>Pinus sylvestris</i> (mean: 70.1% – GI, 67.8% – GII, 64.5% – GV); NAP content ranges from few (GI and GV) to several (GII) percent – dominant by Poaceae, Cyperaceae and <i>Artemisia</i>. Herbaceous taxa such as <i>Dryas octopetala</i>, <i>Helianthemum</i> and <i>Selaginella selaginoides</i> are recorded (Figs. 4–6).</p> <p style="text-align: center;"><u>Concentration of pollen grains:</u> GI: attains $50 \times 10^5/\text{cm}^3$, GII: attains ca. $75 \times 10^5/\text{cm}^3$, GV: attains ca. $30 \times 10^5/\text{cm}^3$</p> <p style="text-align: center;"><u>Macro–remain analysis:</u></p> <p>GI: moss peat with <i>Aulacomnium palustre</i> as main component (873–865 cm) GII: frequency of plant remains increases; numerous remains of trees and shrubs, including <i>Betula nana/humilis</i>; occurrence of endocarps of <i>Potamogeton</i>, abundant remains of Characeae, <i>Daphnia</i> and <i>Cristatella mucedo</i> as well as small pieces of charcoal.</p>

			<p>GV: moss peat with <i>Aulacomnium palustre</i> as main component</p> <p><u>Radiocarbon dating:</u></p> <p>GI: depth of 870–868 cm, 13228–11220 cal BP (95.4%) (10550 ± 410 BP conv., Gd–18499) – organic sediment was dated.</p> <p>GII: depth of 1501 cm, 13450–12745 cal BP (95.4%) (11260 ± 190 BP conv., GdS–602) – organic sediment was dated;</p> <p>depth of 1494 cm, 13419–12707 cal BP (95.4%) (11170 ± 210 BP conv., Gd–30154) – organic sediment was dated.</p>
Younger Dryas 12680– 11590 ¹ /11500 ² cal BP	GI: 860–850; GII: 1475–1405.	GI: carbonate gyttja; GII: detritus (to 1470 cm) and mineral gyttja.	<p><u>L PAZ:</u> GI: <i>Juniperus–Artemisia</i>, GII: <i>Juniperus–Artemisia</i>.</p> <p><u>Pollen spectra:</u></p> <p>G: variable content of <i>Pinus</i> and <i>Betula</i>; absolute maximum of <i>Juniperus</i>; high content of <i>Betula nana</i> and <i>Salix</i>. NAP content increases to several percent (nearly 15% – GI, exceeds 25.0% – GII) and dominated by Poaceae, Cyperaceae and <i>Artemisia</i>. Chenopodiaceae, Apiaceae, <i>Dryas octopetala</i>, <i>Helianthemum</i>, <i>Saxifraga</i> are observed. Redeposited pollen grains of <i>Corylus avellana</i>, <i>Ulmus</i>, <i>Tilia</i> and <i>Alnus</i> are found (Figs. 4 and 5).</p> <p><u>Concentration of pollen grains:</u></p> <p>GI: attains ca. $150 \times 10^5/\text{cm}^3$, GII: attains ca. $50 \times 10^5/\text{cm}^3$.</p> <p><u>Macro-remain analysis:</u></p> <p>GII: decrease in the amount of remnants; only remains of aquatic invertebrates, such as <i>Daphnia</i>, and <i>Cristatella mucedo</i>, are numerous.</p> <p><u>Radiocarbon dating:</u></p> <p>GII: depth of 1439 cm, 13323–13085 cal BC (95.4%) (11370 ± 60 BP conv., Poz–43480) – organic sediment was dated.</p>
Preboreal 11500–10200 ² cal BP	GI: 850–810; GII: 1405–1340; PI: 900–790.	GI: carbonate (to 840 cm) and mineral gyttja (to 820 cm), lacustrine sand (very high content of medium– and coarse–grained sand at 820–810 cm); GII: mineral (to 1400 cm) and carbonate gyttja; PI: gray organic silt separated a sharp boundary (890 cm) from mineral (to 840 cm) and carbonate gyttja.	<p><u>L PAZ:</u> GI: <i>Betula–Pinus</i>, GII: <i>Pinus–Betula</i>, PI: <i>Pinus–Betula</i>.</p> <p><u>Pollen spectra:</u></p> <p>G: <i>Betula</i> attains its absolute maximum (67.2% – GI, 63.5% – GII); constants curves of <i>Alnus</i>, <i>Corylus avellana</i>, <i>Quercus</i> and <i>Ulmus</i> appear. NAP content attains a mean of few percent and is dominated by Poaceae, Cyperaceae and <i>Artemisia</i> (Figs. 4 and 5).</p> <p>P: variable content of <i>Pinus</i> and <i>Betula</i>; constant curves of <i>Salix</i>, <i>Corylus avellana</i> and <i>Quercus</i>. Sporomorphs of <i>Ephedra</i>, <i>Juniperus communis</i> and <i>Hippophæe rhamnoides</i> appear occasionally. NAP content attains a mean value of ca. 10%, with the highest values for Poaceae and <i>Artemisia</i>. The constant curve of Apiaceae disappears; pollen grains of <i>Dryas octopetala</i>, <i>Helianthemum</i> and Chenopodiaceae are found occasionally (Fig. 7).</p> <p><u>Concentration of pollen grains:</u></p> <p>GI: attains ca. $250 \times 10^5/\text{cm}^3$, GII: exceeds $350 \times 10^5/\text{cm}^3$, PI: attains ca. $120 \times 10^5/\text{cm}^3$.</p> <p><u>Radiocarbon dating:</u></p> <p>PI: depth of 890 cm, 20547–20010 cal BP (95.4%) (16810 ± 100 BP conv., Poz–46879) – organic sediment was dated.</p>
Boreal 10200–9600 ² cal BP	GI: 810–740 cm GII: 1340–1070 cm GV: 476–466 cm; PI: 790–712 cm.	GI: mineral (to 780 cm), carbonate (to 760 cm) and detritus gyttja; GII: carbonate (to 1140 cm) detritus gyttja; GV: carbonate gyttja; PI: carbonate gyttja.	<p><u>L PAZ:</u> GI: <i>Corylus–Ulmus</i>, GII: <i>Corylus–Ulmus</i>, GV: <i>Corylus–Ulmus</i>, PI: <i>Corylus</i>.</p> <p><u>Pollen spectra:</u></p> <p>G: few (GV) to several (GI, GII) percent high content of <i>Corylus avellana</i>; content of <i>Ulmus</i> and <i>Quercus</i> increases; curves of <i>Tilia</i>, <i>Fraxinus</i> and <i>Alnus</i> appear (Figs. 4–6). NAP content attains ca. few percent.</p> <p>P: content of <i>Corylus avellana</i> attains a mean of 10.2%; content of <i>Quercus</i> and <i>Ulmus</i> increases; curves of <i>Tilia</i>, <i>Fraxinus</i> and <i>Alnus</i> appear (Fig. 7). NAP content attains ca. few percent.</p> <p><u>Concentration of pollen grains:</u></p> <p>GI: attains ca. $350 \times 10^5/\text{cm}^3$, GII: exceeds $400 \times 10^5/\text{cm}^3$, GV: attains ca. $220 \times 10^5/\text{cm}^3$, PI: attains ca. $120 \times 10^5/\text{cm}^3$</p>
